# Basis of Report

This document has been prepared by SLR Consulting Limited (SLR) with reasonable skill, care and diligence, and taking account of the timescales and resources devoted to it by agreement with Carn Fearna Wind Farm Ltd (the Client) as part or all of the services it has been appointed by the Client to carry out. It is subject to the terms and conditions of that appointment.

SLR shall not be liable for the use of or reliance on any information, advice, recommendations and opinions in this document for any purpose by any person other than the Client. Reliance may be granted to a third party only in the event that SLR and the third party have executed a reliance agreement or collateral warranty.

Information reported herein may be based on the interpretation of public domain data collected by SLR, and/or information supplied by the Client and/or its other advisors and associates. These data have been accepted in good faith as being accurate and valid.

The copyright and intellectual property in all drawings, reports, specifications, bills of quantities, calculations and other information set out in this report remain vested in SLR unless the terms of appointment state otherwise.

This document may contain information of a specialised and/or highly technical nature and the Client is advised to seek clarification on any elements which may be unclear to it.

Information, advice, recommendations and opinions in this document should only be relied upon in the context of the whole document and any documents referenced explicitly herein and should then only be used within the context of the appointment.

# 1.0 Introduction

## 1.1 General

SLR Consulting Ltd (SLR) was commissioned by Carn Fearna Wind Farm Ltd (the 'Applicant') a wholly owned subsidiary of Statkraft UK Limited, to undertake a Peat Landslide Hazard and Risk Assessment (PLHRA) for the proposed Carn Fearna Wind Farm (the Proposed Development). The Applicant is proposing to submit a Section 36 application to construct and operate a 9-turbine wind farm (of which five are up to 200 m blade tip height, and four are up to 180 m blade tip height), energy storage and associated infrastructure, with a combined rated output in the region of 64.8 MW. The location of the Proposed Development is shown on **Figure 10.1.1** with the red line defining the Proposed Development boundary.

The purpose of this report is to consider the extent of peat and potential peat slide hazard at the Proposed Development and consider the potential impact to any development, such that areas of deep peat and areas at higher risk of a peat landslide can be avoided during the design phase. Further consideration is also given to stability risks due to construction of the development and potential risks to receptors in and across the Proposed Development.

The assessment has been undertaken in line with best practice guidance[1,2] issued by the Scottish Government for investigation, assessment and reporting for wind farms in peat areas. Where relevant, reference is also made to guidance published by the Scottish Environment Protection Agency (SEPA) and wind farm construction good practice guidance.

The work has been undertaken by a team of Geotechnical Engineers and Geologists, with over 10 years' experience in undertaking peat assessments. The team was led by a Chartered Hydrogeologist with 30 years' consultancy experience and specialising in the assessment of soils, geology, and water for renewable power projects in Scotland.

## 1.2 Proposed Development

The Proposed Development is shown on **Figure 10.1.2a-c** and comprises the construction of the following infrastructure elements:

- Up to 9 wind turbines and associated foundations;
- crane hardstanding and temporary laydown areas;
- new and upgraded access track;
- temporary construction compounds;
- batching plant;
- underground cabling and electrical infrastructure;
- on-site substation compound;
- search areas for up to three borrow pits;
- off-site turning circle for Abnormal Indivisible Load (AIL) vehicles.

Full details of the Proposed Development are provided in the **EIA Report Volume 2: Chapter 3: Description of the Development**.

Statkraft Internal

## 1.3 Scope and Objectives of Report

The purpose of this report is to identify those areas of the Proposed Development that are naturally susceptible to a higher risk of peat instability so that they can be avoided or accommodated during the design phase. It should be noted that all peat slopes have a risk of instability, and the vast majority of peat slope failures occur naturally.

This peat stability assessment is primarily concerned with the influence of the peat on the development of the wind farm. The main objective is to assess the potential peat stability at the Proposed Development, identify areas of potential concern and identify mitigation measures to ensure the maintenance of peat stability before, during and after construction.

It is important to note that peat instability and the impacts of any instability are not constrained by artificial site or ownership boundaries but by topographic and geomorphologic boundaries. It is therefore important to ensure that the breadth of scope of any assessment adequately covers the areal extent of possible impact.

The peat depth interpolation and peat slide risk calculation areas extend out to a maximum extent defined as 100 m from each peat depth survey point, with consideration of wider assessment areas not defined by distance but by review of geomorphology with review of hydrological and topographic boundaries which are factors influencing the peat stability assessment.

The risk assessment is based on ground models developed using a Geographical Information System (GIS) specifically for this Proposed Development. A numerical analysis was undertaken in which coefficients were allocated for each of the factors influencing peat stability.

The conceptual layout of the Proposed Development was considered alongside the findings from the peat probing, sampling and analysis by the design team to optimise the Proposed Development layout and associated access to avoid or mitigate areas of unacceptable peat slide risk. The layout presented in the drawings represents the final iteration of the scheme layout.

This system outlined above was developed in accordance with the guidelines on PLHRA by the Scottish Government[1] for the investigation, assessment, and reporting for wind farms in peat areas. The analysis and interpretation are based upon the results obtained from this process as well as previous experience and the results of case studies elsewhere. Where deviations from this guidance have occurred, this is highlighted and explained in the text.

The objectives have been achieved by completion of the following scope of works:

- a desk-based review of available reports which include geological, hydrological and topographical information;
- peat depth surveys and peat augering;
- geomorphological mapping of the Proposed Development to identify the prevailing conditions influencing the potential for, or any evidence of, active, incipient or relict peat instability, including identification of the location and photographic record, as appropriate;
- reporting on evidence of any active, incipient or relict peat instability, and the potential risk of future instability, describing the likely causes and contributory factors;
- identification of potential controls to be imposed on the Contractors for the Works to minimise the risk of peat instability occurring at the Proposed Development; and

Statkraft Internal

- provide recommendations for further work or specific construction methodologies to suit the ground conditions at the Proposed Development to mitigate any significant risk of potential peat instability.

Construction of the Proposed Development would only increase the risk of peat slope instability if good geotechnical construction practice is ignored, and it is a requirement of all power infrastructure developments to follow a very carefully worded and designed Construction and Environmental Management Plan (CEMP) which incorporates the recommendations of the PLHRA.

Without the guidance contained in a Construction Method Statement or CEMP, the following factors could increase the risk of instability:

- construction of access tracks;
- installation of wind turbines and associated infrastructure;
- stockpiling of peat and loading of slopes; and
- blocking of natural drainage, inappropriate new drainage or drainage discharge.

Statkraft Internal

# 2.0 Peat Instability

The importance of assessing the stability of peat deposits in relation to wind farm developments came to the fore as a result of peat failures during the construction of Derrybrien[3] Wind Farm in Ireland in 2003. Although no fatalities were associated with these failures, there was a significant environmental impact. Wind farms tend to be constructed in upland areas which may be associated with significant peat deposits (typically blanket bogs). There is a potential for peat instability to occur, particularly where deposits are in excess of 1m thick.

Peat instability is influenced by many factors, including, but not limited to, peat thickness, hill slope gradient, underlying geology and subsurface hydrology.

This section reviews the nature of peat and how current and past activities can influence stability. The factors which are likely to influence the potential for peat instability are:

- Significant peat depths over impermeable bedrock or minimal soil.
- The presence of slope gradients greater than $2^{o}$ (approximately) and general topography.
- Natural drainage paths.
- Evidence of past failures, including soil creep.
- Drainage features at the base of slopes which could lead to undercutting.
- Forestry plantations and artificial drainage and recent climate patterns.

It should be noted that peat instability is not a recent phenomenon and there is documentary evidence of peat landslides dating back over 500 years[4]. Many landslides that involve peat have no human interference that could be considered as a trigger, and this should be borne in mind when considering the susceptibility of a site to potential instability.

## 2.1 Background Information Regarding Peat

### 2.1.1 Definition of Peat

Peat is defined as an organic soil comprising the partly decomposed plant remains that have accumulated in-situ, rather than being deposited by sedimentation. When peat forming plants die, they do not decay completely as their remains become waterlogged due to regular rainfall. The effect of waterlogging is to exclude air and hence limit the degree of decomposition. Consequently, instead of decaying to carbon dioxide and water, the partially decomposed material is incorporated into the underlying material and the peat 'grows' in-situ.

The Scottish Government Peat Landslide Hazard Best Practice Guide (2017) uses the following Joint Nature Conservation Committee (JNCC) report 455 'Towards an Assessment of the State of UK Peatlands' definition for classification of peat deposits:

- Peaty (or organo-mineral) soil: a soil with a surface organic layer less than 0.5 m deep;
- Peat: a soil with a surface organic layer greater than 0.5 m deep which has an organic matter content of more than 60 %; and
- Deep Peat: a peat soil with a surface organic layer greater than 1.0 m deep.

Statkraft Internal

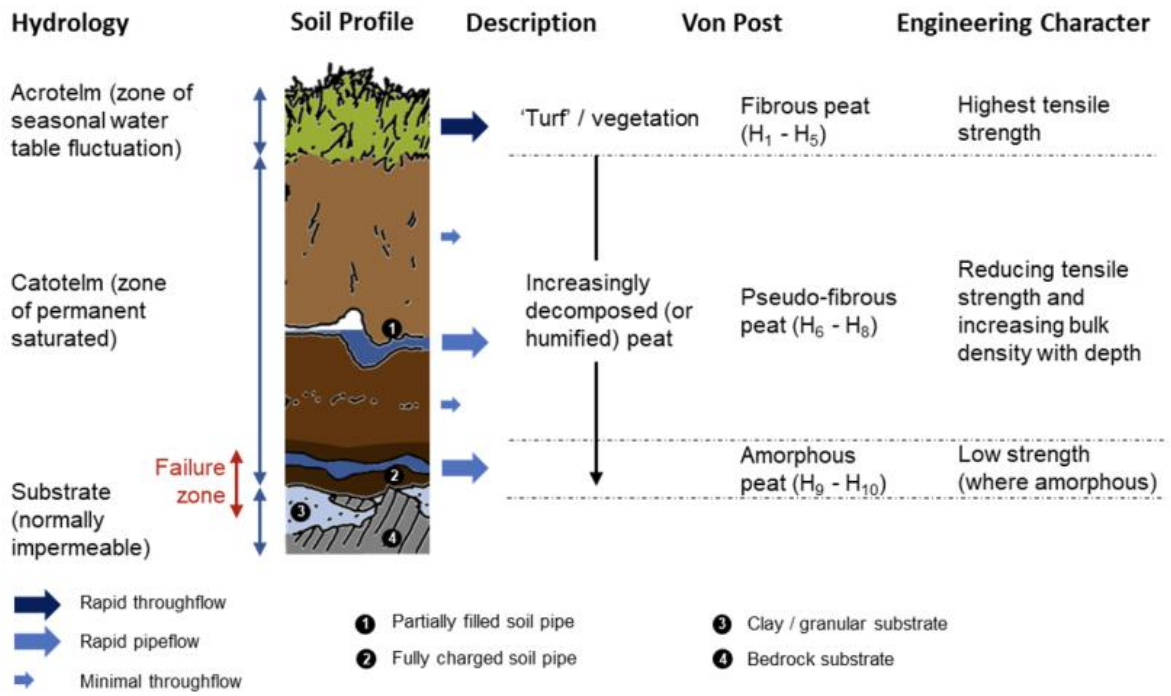

Peat is characterised by low density, high moisture content, high compressibility and low shear strength, all of which are related to the degree of decomposition and hence residual plant fabric and structure. To some extent, it is this structure that affects the retention or expulsion of water in the system and differentiates one peat from another.

Lindsay[5] defined two main types of peat bog, raised bog and blanket bog, which are prevalent on the West coast of Europe along the Atlantic seaboard. In Britain, the dominant peatland is blanket bog which occurs on the gentle slopes of upland plateaux, ridges and benches and is predominantly supplied with water and nutrients in the form of precipitation. Blanket peat is usually considered to be hydrologically disconnected from the underlying mineral layer.

There are two principal types of peat in a near natural peatland (see **Plate 1 below**):

- The upper (acrotelm) layer in which the water table fluctuates, which is fibrous and comprises plant roots etc. The acrotelm is relatively dry and has some tensile strength and its thickness typically ranges from 0.1 m to 0.6 m deep.
- The lower (catotelm) layer, which is saturated, sitting permanently below the water table. The catotelm layer is highly decomposed, generally becoming more amorphous/liquid in nature and losing structure with increasing depth. The structure of catotelmic peat tends to disrupt completely on excavation and handling.

**Plate 1 - Typical Peat Profile[6]**

The acrotelm is the fibrous surface to the peat bog[7], typically less than 0.6 m thick, which exists between the growing bog surface and the lowest position of the water table in dry summers.

Statkraft Internal

For geotechnical purposes the degree of decomposition (humification) can be estimated in the field by applying the 'squeezing test' proposed by von Post and Grunland[8] (1926) and as shown in Plate 1. The humification value ranges from H1 (no decomposition) to H10 (highly decomposed). The extended system set out by Hobbs[9] provides a means of correlating the types of peat with their physical, chemical and structural properties.

The relative position of the water table within the peat controls the balance between accumulation and decomposition and therefore its stability, hence artificial adjustment of the water table by drainage requires careful consideration.

### 2.1.2 Peat Shear Strength

In geotechnical terms, the shear strength of a soil is the physical characteristic that provides stability and coherence to a body of soil. For mineral soils such as clays or sands, such strength is variously given by an inter-particle friction value and cohesion. Depending on whether the mineral soil is predominantly cohesive (clay) or non-cohesive (sand) governs which of the components of strength control the behaviour of the soil.

For peat soils, where the major constituent is organic and there is likely to be little or no mineral component, the geotechnical definition of shear strength does not strictly apply. At present there is no real alternative method for defining the shear strength of peat, therefore the geotechnical definition is generally adopted, in the knowledge that it should be used with great caution.

As noted previously, the acrotelm or near surface peat comprises a tangle of fresh and slightly rotted roots and vegetable fibres. These roots and fibres impart a significant tensile shear strength capacity to the material which provides it with a significant load carrying capacity. The acrotelm is, in effect, a fibre reinforced soil.

In the more decomposed catotelm, the tensile shear strength is reduced as the roots and fibres become more rotted. However, the loss in strength due to decomposition is offset to a limited degree, by a gain in strength due to the overburden pressure. In geotechnical engineering there is an established relationship for recently deposited soils, between the shear strength of a sample and the thickness of overburden above it.

Consequently, it is almost impossible to predict a shear strength profile in peat and attempts to measure the shear strength using normal geotechnical methods can be misleading. Typical values of shear strength from hand shear vanes would be in the range 10-60 kilopascal (kPa) although values over 100 kPa have been recorded in peat elsewhere. The higher strengths are almost certainly the influence of roots or other non-decomposed material. It is believed that the strength of peat should be quoted as a cohesion value as there are few, if any, discrete particles to give the material a significant frictional resistance. It should be noted, however, that any quotation of shear strength for peat should be treated with extreme caution.

### 2.1.3 Peat Stability-Factors to be Considered

There is considerable observational information relating to debris and peat flows although the actual mechanisms involved in peat instability are not fully understood. The main influences on slope stability are geological, geotechnical, geomorphic, hydrological, topographic, climatic, agricultural and human influences such as drainage and construction activity. Peat is affected to a degree by changes in any of the above list and it is vital to appreciate that changes to the existing equilibrium would affect the level of slope stability during construction and operation of the Proposed Development.

9 Hobbs, N.B., (1986), 'Mire morphology and the properties and behaviour of some British and foreign peats.' Quarterly Journal of Engineering Geology, London, 19, 7-80.

Statkraft Internal

Some of the contributory factors to peat instability are summarised as follows:

- The geographical limits which could be affected by potential instability are not confined to the artificial boundaries imposed by land ownership; landslip occurring above a site could affect the site and property down slope or downstream of the site for several kilometres.
- Agriculture and grazing have a substantial effect on peat areas, and this can be compounded in areas that have been managed to improve grazing. Grazing compacts the peat surface reducing the rainwater infiltration and the additional nutrients change the ecological balance of the original peat bog. Agricultural management can include surface drainage and periodic burning, both of which can leave the surface of the peat bare for a period of time, resulting in temporary desiccation of the surface. Subsequent wetting of the peat and resumption of peat accumulation results in the former desiccated and possibly ash covered surface being incorporated into the body of the peat which introduces a weak discontinuity in the profile; this in turn becomes another unknown factor in the stability assessment.
- Forestry has a substantial effect on slope stability particularly in the early stages as the creation of a forest involves disruption of the natural equilibrium and drainage of the slopes and the installation of artificial drains by deep ploughing. The construction of access tracks further disrupts the drainage and concentrates groundwater flow into narrow, fast flowing erosive streams. The work by Winter *et al* [10] noted that forest tracks can act to retard or concentrate the down slope flow of water and thus aid its penetration into the slope below. Such a mechanism has been observed at a number of recent landslips that have affected the road network in Scotland.
- Natural drainage – some of the precipitation falling onto a natural upland peat bog would be absorbed into the low permeability catotelm peat. However, most of the water would run-off as sheet flow through upper, high permeability acrotelm. Thus, the water is transmitted to the lower slopes in a reasonably controlled manner through a range of interconnections that operate at different scales and speed. Failure to understand this and to disrupt the transmission process for the groundwater could result in instability.
- Artificial drainage - where agricultural drainage has been used to improve the quality of the grazing or to promote forestry, it reduces the overall volume of water entering the bog and transfers this water to the edges more rapidly. This can result in ditches and streams becoming enlarged, causing increased erosion and a greater silt burden in the stream water.

## 2.2 Peat Mass Stability

The principal surface indicator of peat slide potential is cracking of the peat land surface, and it is the identification of crack patterns in the field and the attendant causes of the cracking that is fundamental to a peat stability assessment.

Sites that have exhibited natural instability in the past are likely to be more susceptible to future instability during and following construction of a renewable energy development, therefore it is important to identify such instability as part of the Peat Stability Assessment.

Statkraft Internal

### 2.2.1 Types of Failure

The result of instability in peat is the down-slope mass movement of the material; there are a number of definitions of peat instability which are used to characterise the type of failure including:

- Bog bursts or bog flows – the emergence of a fluid form of well humified, amorphous peat from the surface of a bog, followed by the settling of the residual peat, in-situ [11].
- Peat slides – the failure of the peat at, or below, the peat/substratum interface leading to translational sliding of detached blocks of surface vegetation together with the whole underlying peat stratum[11].
- Bog slide – an intermediate form of instability where failure occurs on a surface within the peat mass with rafts of surface vegetation being carried by the movement of a mass of liquid peat.

### 2.2.2 Bog Bursts

Accounts of bog bursts are generally associated with very wet climates or areas which have received storm rainfall events. Bog bursts can be associated with particularly wet peat landscapes; therefore, it is possible to identify broad regions of a higher susceptibility to these failures. The constraints used to identify the areas of higher susceptibility to bog burst failure are given below:

- Peat thickness greater than 2 m.
- Shallow gradients, generally within the range of 2 to 5°, peat thicker than 1.5 m is generally not observed on slopes steeper than 10°, also moisture content is generally reduced on steeper slopes due to drainage.
- Ground which is annually waterlogged to within the upper 1 m below ground level (bgl) (the groundwater level may rise above this but rarely falls below).
- Greater humification of the lower catotelm within the waterlogged ground; and lower surface tensile strength of the fibrous peat and vegetation.

The humified mass can be considered as analogous to a heavy liquid and the stability of this mass is maintained by the strength of the surface or acrotelm peat. Should the surface become weakened through erosion or desiccation or the construction of a surface drainage ditch for agricultural or forestry reasons or through turbary (peat cutting), failure is made more likely.

### 2.2.3 Peat Slides

Peat slides tend to be translational failures with a defined shear surface at or close to the interface with the substrate.

The factors generally considered to influence susceptibility to peat slide failures are listed below:

- Peat depth up to 3 m.
- Slope gradients between 4.5$^{o}$ and 15$^{o}$.
- Natural or artificial drainage cut into the surrounding peat landscape.
- Greater humification of the lower catotelm within the waterlogged ground.

11 Dykes, A.P and Kirk, K.J., (2001), 'Initiation of a multiple peat slide on Cuilcagh Mountain, Northern Ireland.' Earth Surface Processes and Landforms, 26, 395-408.

Statkraft Internal

- Lower surface tensile strength of the fibrous peat and vegetation.

It is noted that some of the factors causing instability are common to both bog bursts and peat slides.

The peat – substrate interface is the primary zone of failure and is enhanced by elevated water content at this boundary and softening or weathering of the lower mineral surface. For this reason, any investigation or probing should try to distinguish the nature of the lower mineral substrate.

### 2.2.4 Bog Slides

A bog slide is a variation on a peat slide where part of the peat mass is subject to movement, usually on an internal layer of material, which may be more prone to movement, such as an interface between the acrotelm and catotelm layer.

### 2.2.5 Natural Instability

The stability of a peat mass is maintained by a complex inter-relationship of many factors. Key factors include sloping rock head and proximity to a water body. Rainfall often acts as the trigger after the slope has already been conditioned to fail by natural processes.

It should also be remembered that peat bogs are growing environments and that there would come a time, on sloping ground, where the forces causing instability, the weight of the bog, can no longer be resisted by the internal strength of the peat and its interface with the underlying mineral surface. At this point, failure would occur.

The weight of the peat bog or any soils mantling steep hill slopes would be increased during periods of very heavy rain and it is common to see landslips occurring following extreme rain events. This may be a concern for future developments where one of the predicted effects of global warming will be a greater frequency of extreme weather, intense storms being one element.

Statkraft Internal

# 3.0 Desk Based Review

## 3.1 Site Description

The Proposed Development is located approximately 1.5 km from Garve and 6 km north-east of Contin within the Highland Council (THC) local planning authority area. The Proposed Development is characterised by large areas of heathland, rough hill pasture and a small localised area of coniferous plantation forestry located in the north and more plantation forestry on the access track to the main area of the Proposed Development. The topography is typically formed of steep slopes on the main access track which then level out to a plateau with rounded hills, outcropping crags and lochans at the base of the slopes up to Little Wyvis and Carn Gorm to the north-west. Three lochans exist within the central area of the Proposed Development. The highest elevation is at Beinn a' Ghuilbein at 471 m Above Ordnance Datum (AOD), the lowest elevation is to the south of Allt Cnoc nan Cleireach on the access to the Proposed Development from Silverbridge at 112 m AOD.

## 3.2 Geology and Soils

### 3.2.1 Artificial Ground

Based on the information available from the British Geological Survey (BGS) Geoindex[12], no made ground deposits are noted across the Proposed Development.

### 3.2.2 Superficial Geology

Based on the available BGS online data[12] there is an absence of mapped superficial deposits across large parts of the Proposed Development, mainly across steep slopes and hilltops. Glacial till is mapped across the Proposed Development, generally at lower elevations. Minor Alluvium deposits are also mapped in the north-west near the watercourses at the access entrance and River Terrace Deposits at the off-site turning circle. Peat deposits are extensively mapped across central areas of the Proposed Development but not recorded at the off-site turning circle.

**Figure 10.1.3a-c** shows the superficial geology BGS mapping and the Proposed Development.

### 3.2.3 Bedrock Geology

Based on the available BGS online data[12] the Proposed Development is underlain by a number of different bedrock formations as detailed below:

- Glenfinnan Group – Psammite and Semipelite; the most common bedrock formation covering large parts of the Proposed Development.
- Garve Psammite Formation – Psammite; mapped along main access track and track towards T1 near Beinn a' Ghuilbein.
- Vaich Pelite Formation – Semipelite; mapped at main access track to north of Allt Abhagaith.
- Crom Psammite Formation – Psammite; mapped in the north-west at access entrance.
- Unnamed Metamorphic Rocks – Gneiss; mapped only on main access track at Glac Bhan.

12 BGS Online Viewer, available at [https://mapapps2.bgs.ac.uk/geoindex/home.html?_ga=2.133433804.376188765.1646739904-1030004651.1646739904]

Statkraft Internal

- Carn Chuinneag And Inchbae Augen Gneiss – Granite Gneissose at the off-site turning circle only.

No igneous intrusions are mapped directly within the main Proposed Development area.

One major fault is inferred south-west to north-east in the north-west of the Proposed Development.

**Figure 10.1.4a-c** shows the bedrock geology BGS mapping and the Proposed Development.

## 3.3 Peatland Classification

The Carbon and Peatland Map 2016[13] provided in **Figure 10.4a-c Peatland Classification** indicates that large parts of the Proposed Development are located within Class 1 peatland which are considered nationally important carbon-rich soils, deep peat and priority peatland habitats and areas likely to be of high conservation value. These areas are mostly located in the western and southern parts of the Proposed Development where elevations are generally lower. Minor areas of Class 2 peat are noted within northern and southern areas of the Proposed Development. Class 2 (habitats which may contain carbon rich soils and deep peat but are not considered to be of high conservation value). Areas of Class 5 are present across the Proposed Development including the off-site turning circle area. Class 5 indicates no peatland habitat recorded but these areas may also include areas of bare soil and soils are carbon-rich and comprise deep peat.

The Carbon and Peatland Map[13] provides an indication of the likely presence of peatland and should not be used in development management decision making with on-site specific detailed peat surveying and assessment required to determine the presence of peat which is detailed in later sections.

## 3.4 Ground Stability Hazards

BGS Online data[12] records indicate that there is no risk regarding the mass movement or instability of materials.

## 3.5 Mining and Quarrying

Information from The Coal Authority Online Viewer[14] indicates that the Proposed Development is not within a coal mining reporting area.

BGS Online data[12] indicate there are no historical pits located within the Proposed Development.

## 3.6 Hydrogeology

BGS Online data[12] records indicate that the entirety of the Proposed Development is underlain by metamorphic rocks of the Loch Ness Supergroup. These rock types are classified as a low productivity aquifers whereby small amounts of groundwater are expected near surface weathered zones and secondary fractures. The superficial deposits of Glacial Till are not considered a significant aquifer. However, alluvial deposits mapped can store groundwater and permit groundwater movement through the sand and gravel horizons. This intergranular flow results in localised areas of moderate to high productivity aquifers.

## 3.7 Hydrology

The Proposed Development is located within the surface water catchments of the Loch na Croic and Loch Garve (ID: 100134) which drain the central and southern areas of the Proposed Development. The northern areas of the Proposed Development are drained by the sub-catchment of the Black Water – Loch Garve to Garbat (ID: 20180).

## 3.8 Rainfall

SEPA have provided precipitation data[15] for Dingwall rainfall gauge (station number 115329) which is located approximately 13 km south-east of the Proposed Development.

**Image 2: Monthly Rainfall totals in mm from Dingwall Station**

## 3.9 Groundwater Dependent Terrestrial Ecosystems (GWDTE)

As detailed in **EIA Volume 2, Chapter 10: Geology, Hydrology Hydrogeology and Peat**, as no GWDTE are sustained by groundwater they are not at risk from the Proposed Development.

## 3.10 Private Water Supplies

As detailed in **EIA Volume 2, Chapter 10: Geology, Hydrology Hydrogeology and Peat**, there are three private water supplies (PWS) in the vicinity of the Proposed Development. Only one is at potential risk from the Proposed Development and is located adjacent to existing track which are scheduled to be upgraded (NH 40794 64113). Further details are provided within the chapter.

## 3.11 Environmental Designations

Information from Scotland's Environment Online Map Viewer[16] confirms that no designated sites are located within the Proposed Development.

## 3.12 Geomorphology

The Proposed Development is generally characterised by an upland plateau surrounded by a number of summits to the north such as Little Wyvis at 764 m AOD and Carn Gorm at 556 m AOD. The Proposed Development also contains frequent bedrock outcrops, wide ridges and small incised gulleys, with flatter expanses existing in the slope breaks and topographic lows between the bedrock outcrops and hillslopes. Lochans and areas of peat have formed within these flatter expanses and localised hollows between bedrock outcrops. **Photographs 1, 2 and 3** display the typical conditions at the Proposed Development.

Geomorphological mapping is detailed on **Figure 10.1.5a-c**. Typical conditions observed throughout the Proposed Development are detailed below in the following photographs.

**Photograph 1: Overview of the Proposed Development looking south to Loch a'Bhealaich from National Grid Reference (NGR): NH 42598 63008.**

**Photograph 2: Overview of the Proposed Development looking north from T8 towards Meal Odhar Beag. NGR: NH 42736 62176.**

Statkraft Internal

**Photograph 3: Overview of the Proposed Development looking north from NGR: NH 42612 62156.**

### 3.12.1 Peat Deposits

Peat deposits are common throughout the Proposed Development, with more extensive areas recorded across the flatter lying areas of the upland plateau. There is an area of extensive peat in the north of the Proposed Development to the west of the turbine array T1, T2 and T3 and around T6 with deep peat >2.5 m recorded. Peat deposits were also recorded in the

Statkraft Internal

southern area of the Proposed Development to the west of T8 and to the south-west of T9 as peat >3 m recorded. There are localised hollows of peat across the Proposed Development. These pockets of deeper peat are to the south-west of T7 and north of the proposed substation, with peat >3 m mapped. Pockets of peat located to the north of T1 and at the temporary construction compound record depths of >2 m. **Photograph 4** shows the typical peatland conditions to the south of Carn Loch an Turic.

No areas of instability were noted in relation to the peat deposits recorded across the Proposed Development.

Further details on peatland habitats are described within **EIA Report Volume 2: Chapter 8: Ecology.**

**Photograph 4: Overview of the peatland looking south-west from NGR: NH 41940 62419.**

### 3.12.2 Peat Erosional Features

There are areas of peat hagging across the Proposed Development, mainly within the north on more exposed slopes. Gully erosion and some hagging is located to the west and north of T6 (**see Photograph 5**) where extensive erosion has led to areas of bare peat. Peat depths recorded were between 1-2 m, with hagging measuring similarly mapped. Furtherly, smaller scale hagging was seen to the west of T1 and to the north of the temporary construction compound, mainly constrained to areas near watercourses.

Based on site observations, the gully erosion and hagging observed is likely to be exacerbated by wind erosion due to the topographically exposed nature of this area and higher elevations. In addition, there is evidence of hydrologically influenced gully erosion due to localised networks of drainage across the peatland.

Statkraft Internal

No areas of instability were noted in relation to any erosional features across the Proposed Development.

**Photograph 5: Gully erosion and peat pan looking west towards T6. NGR: NH 42167 62940.**

### 3.12.3 Drainage

There was natural drainage at localised areas through peat pipes, some of which had failed and created depressions. The peat pipes were measured at between 1 - 1.5 m width and were not active at time of survey (**See Photograph 6**).

The Proposed Development features anthropogenic drainage along the main access track. These drainage ditches trend from north to south down along the access track. The artificial ditches were measured at 0.5 m deep and 0.8 m wide (**Photograph 7**). There was additional active drainage along the existing access track in the form of furrows and culverts running perpendicular to the track discharging into watercourses.

No areas of instability were noted in relation to drainage across the Proposed Development.

Statkraft Internal

**Photograph 6: Peat pipe at borrow pit on Beinn a'Ghuilbein. NGR: NH 42181 63455.**

**Photograph 7: Drainage ditch trending north-south trackside at Allt Abhagaith from NGR: NH 41858 63893.**

### 3.12.4 Cuttings

Peat cuttings were not observed during a review of the aerial photography or site visits.

Statkraft Internal

### 3.12.5 Forestry

Forestry is not common across the Proposed Development. There are areas of localised forestry plantation and native forestry in the north of the Proposed Development near the main access track (see **Photograph 8)**. However, there is extensive forestry located to the west of the Proposed Development at Torr Beithe.

No areas of instability were noted in relation to forestry across the Proposed Development.

**Photograph 8: Planation forestry viewed from main access track looking west from NGR: NH 40524 63929.**

### 3.12.6 Bedrock

From review of aerial photography, bedrock outcrops are abundant across the Proposed Development. This was confirmed during site walkovers where bedrock outcrops were frequently encountered. Bedrock was often seen on the tops of ridges and flatter tops. Mostly bedrock was observed as weathered regolith or at near surface (see **Photograph 9**).

No areas of instability were noted in relation to bedrock exposures across the Proposed Development.

Statkraft Internal

**Photograph 9: Exposed bedrock looking west from NGR: NH 42955 62108**

### 3.12.7 Extension/Compression Features

It was not possible to identify evidence of any significant historic peat failures or slides at the Proposed Development from the aerial photographs and this was confirmed during site visits with no evidence of any extension or compression features identified in the peat during site visits.

Statkraft Internal

# 4.0 Site Work

## 4.1 Peat Depth Survey

Peat surveys were carried out in accordance with best practice guidance for developments on peatland[17,18]. Phase 1 peat probing was conducted on a 100 m grid to allow for initial assessment of the Proposed Development and for use in preliminary site layout designs. Phase 2 peat probing was conducted using targeted grids across infrastructure and tracks.

Surveys were undertaken by SLR with the thickness of the peat assessed using a graduated peat probe, approximately 6 mm diameter and capable of probing depths of up to 10 m. This was pushed vertically into the peat to refusal and the depth recorded, together with a unique location number and the co-ordinates from a handheld Global Positioning System instrument (GPS). The accuracy of the GPS was quoted as ±2 m, which was considered sufficiently accurate for the surveys. All data was uploaded into a GIS database for incorporation into various drawings and analysis assessments.

Where the peat probing met refusal on a hard substrate, the 'feel' of the refusal can provide an insight into the nature of the substrate. The following criteria were used to assess material:

- Solid and abrupt refusal – rock;
- Solid but less abrupt refusal with grinding or crunching sound – sand or gravel or weathered rock;
- Rapid and firm refusal – clay; or
- Gradual refusal – dense peat or soft clay.

The relative stiffness of the peat was also assessed from the resistance to penetration of the probe and to the effort required to extract the probes (retrieval of the probe was often impossible for one person). In all instances refusal was met on obstructions allowing identification of subsurface geology.

## 4.2 Peat Depth

Peat is generally defined as a soil with a surface organic layer in excess of 0.5 m[17]. Where the probing recorded less than 0.5 m thick, it is considered to be a peaty soil (or organo-mineral soil). Soils with a peaty organic horizon over mineral soil are often referred to as 'peaty soils'. These organo-mineral soils are extensive across the UK uplands, but do not meet recognised definitions of peat as they are either shallower than true peat or have a lower carbon density.

The peat was found to vary across the Proposed Development in terms of thickness and coverage. Deeper peat was generally encountered in flatter, lower gradient areas of the Proposed Development. The maximum depth of recorded peat was 4.8 m bgl, recorded adjacent to Loch na Guailne in the south of the Proposed Development. The average thickness of peat recorded across the Proposed Development was 0.6 m. Probing indicated that 60% of peat probe locations encountered <0.5 m of peat. 31% of probe locations identified peat between 0.5 to 1.5 m, and the remaining 9% of probe locations encountered peat depths >1.5 m.

A total of 6,183 peat probes were undertaken across all survey phases, with the results summarised in Table A and presented on the peat depth interpolation figures provided in

17 Scottish Renewables & SEPA (2012) 'Developments on Peatland Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste'.

Statkraft Internal

**Figure 10.1.6a-f** and **Figure 10.1.7a-f**. The interpolation was undertaken using the Spline with Barriers tool in ArcGIS Pro methodology. All probing data is provided in Annex A.

**Table A: Peat Probing Results**

| Peat Thickness (m) | No. of Probes | Percentage (of total probes undertaken on-site) |
|---|---|---|
| 0 (no peat or soil) | 270 | 4.4 |
| 0.01 – 0.49 (peaty soil) | 3467 | 56.1 |
| 0.50 – 0.99 | 1415 | 22.9 |
| 1.00 – 1.49 | 491 | 7.9 |
| 1.50 – 1.99 | 313 | 5.1 |
| 2.00 – 2.49 | 120 | 1.9 |
| 2.50 – 2.99 | 75 | 1.2 |
| 3.00 – 3.49 | 26 | 0.4 |
| 3.50 – 3.99 | 4 | 0.1 |
| > 4.0 | 2 | 0.0 |

## 4.3 Peat Condition

Peat is described using BS5930[19] and the Von Post classification[20]. Four peat cores and samples were collected by SLR during Phase 2, using a peat auger and used to inform interpretations of the underlying physical peat condition and underlying substrate. Peat samples were undertaken to depths of between 1.0 and 2.6 m bgl. From **Table B** the peat augers taken recorded fibrous to pseudo-fibrous condition. The peat augers recorded peat was not dry and cuttings at roadside also supported this conclusion of condition.

**Table B: Peat Coring Results**

| Location | Von Post Degree of Decomposition | Description |
|---|---|---|
| PC01:<br>Access track (north of Meall Ruighe an Fhirich) | H3, B3<br>H4, B3 | GL – 0.50 Brown fibrous PEAT<br>0.50 – 2.00 Dark brown pseudo-fibrous PEAT |

Statkraft Internal

## 4.4 Substrate

Where possible, in the SLR investigation, an assessment of the substrate was made, as described previously. From the evidence of the probing and coring, the substrate was recorded as the following:

- Granular, recorded at 5,782 (94%) probe locations; and
- Rock, recorded at 401 (6%) probe locations.

Based on a review of the BGS mapping and site surveys, the granular material is anticipated to be of glacial till origin and of weathered bedrock (see **Photo 9**). No rock samples were recovered from probe locations however, based on the limited rock exposures and BGS mapping, the bedrock is interpreted to be metamorphic, igneous and sedimentary in nature.

Statkraft Internal

# 5.0 Hazard and Risk Assessment

## 5.1 Introduction

The Scottish Government Guidance[1] provides an overview of the principles of hazard and risk with respect to peat landslides. The guidance is noted as illustrative only and the developers can present their own methodology providing, it is clearly explained and incorporates consideration of the likelihood of instability and the consequences should it occur. The following sections detail the preferred methodology used within this assessment.

A 'Hazard Ranking' system has been applied based on the analysis of risk of peat slide as outlined in the Scottish Government Guidance[1]. This is applied on the principle:

**Hazard Ranking = Hazard x Exposure**

This philosophy can be applied to the assessment carried out so far in the following approach:

**Hazard Ranking = Risk Rating x Impact Rating**

## 5.2 Methodology

The determination of Risk Rating and Impact Rating values is based on a number of variables which impact the likelihood of a peat slide and the relative importance of these variables specific to the Proposed Development.

Similarly, the consequences or exposure to receptors is dependent on variables including the particular scale of a peat slide, the distance it will travel, and the sensitivity of the receptor.

In the absence of a predefined system, the approach to determining and categorising Risk Rating and Impact Rating is determined on a site-by-site basis. The particular system adopted for the PLHRA is outlined in the following sections.

## 5.3 Slope Stability

The stability of peat is a complex subject and there are numerous inter-relationships that affect the stability.

A quantitative assessment requires a numerical input, and such an analysis cannot account for the unquantifiable input required for a comprehensive peat stability assessment. For this reason, a purely quantitative assessment should only be considered as a guide, and a qualitative assessment of stability should be used to inform the final recommendations.

The characteristics of the peat failure phenomena have been incorporated in a stability risk assessment to evaluate the risk of instability occurring within the peat areas. The main factors controlling the stability of the peat mass are the surface gradients, the depth and condition of the peat at each location and the type of substrate.

The natural moisture content and undrained shear strength of the peat are important; however, it is generally accepted that where present, the peat would be saturated and have a very low strength. It is believed to be unrealistic to rely on specific values of shear strength to maintain stability when back analysis of failed slopes indicates that there is often a significant discrepancy between measured strength in peat and stability. Shear strength has been assumed to be constant and worst case, throughout this assessment. It has also been assumed, as a worst case, that the groundwater level is coincident with the ground surface.

Statkraft Internal

## 5.4 Risk Rating

The potential for a peat slide to occur during the construction of the Proposed Development depends on several factors, the importance of which can vary from site to site. The factors requiring considerations would typically include:

- Peat depth;
- Slope gradient;
- Substrate material; and
- Evidence of instability or potential instability;

Of these, peat depth and slope gradient are considered to be principal factors. Without a sufficient peat depth and a prevailing slope, peat slide hazard would be negligible.

The rating system outlined below differs slightly from that proposed in the Scottish Government Guidance[1] as the system adopted here incorporates three inputs compared to two in the guidance, with the potential impact of substrate added in this section.

The probability of a peat landslide 'Risk Rating' (score) was derived by multiplying the coefficients for the four key factors (with historic instability as 1) together to produce a risk rating which is a measure of the likelihood of peat instability, and this enables potential areas of concern to be highlighted. For the assessment, the following rating system was applied as shown in Table C.

**Table C: Probability of Peat Landslide**

| Risk Rating Coefficient | Potential Stability Risk (Pre-Mitigation) | Action |
|---|---|---|
| <5 | Negligible | No mitigation action required. |
| 5 - <16 | Low | As for negligible condition plus development of a site-specific construction and management plan for peat areas. |
| 16 - <31 | Medium | As for low condition plus may require mitigation to improve site conditions. |
| 31-50 | High | Unacceptable level of risk, the area should be avoided. If unavoidable, detailed investigation and quantitative assessment required to determine stability and sensitivity to minor changes in strength and groundwater regime combined with long term monitoring. |
| >51 | Very High | Unacceptable level of risk, the area should be avoided. |

### 5.4.1 Peat Depth

Table D shows the peat depth ranges and their related peat depth coefficients. The ground conditions were assessed by using peat depths recorded during peat probing. Thin peat was classed as being 0.5 to 1.5 m thick, with deposits in excess of this being classed as thick. The thickness ranges used are intended to reflect the risk of instability associated with both peat slides (in thin peat) and bog slides. Where the probing recorded peat less than 0.5 m thick, this has been considered to be an organic soil rather than peat and are outside the scope of this assessment.

In addition to peat thickness, the presence of existing landslip debris or indicators of meta-stable conditions such as tension cracks or slumping in the peat suggest the material is likely

Statkraft Internal

to become even less stable should the existing ground conditions change. Where evidence of historical slips, collapses, creep or flows is seen, a separate coefficient has been applied.

**Table D: Coefficients for Peat Depth**

| Peat Depth Range | Description | Peat Depth Coefficients |
|---|---|---|
| (<0.5 m) | Peaty/organic soil | 0 |
| (0.5 – 1.5 m) | Thin Peat | 2 |
| (>1.5 m) | Thick Peat | 3* |
| - | Slips /collapses / creep / flows | 8 |

***Note that thicker peat generally occurs in areas of shallow gradients and records indicate that thick peat does not generally occur on steeper gradients.**

### 5.4.2 Slope Gradients

Table E gives the coefficients applied to the categorised slope angles. The slope gradients were assessed by reference to the mapping and particularly the Digital Terrain Model (DTM) which was used to generate a slope map (**Figure 10.1.8a-f**), from which the gradient at each probe location could be determined and input into the risk rating spread sheet (**Annex A**). The gradient quoted at each location was based on the average gradient over a 5 m grid.

Coefficients for slope gradient have been assigned to ensure the potential for both peat slides (gradients of 4-15°) and bog slides (gradients of 2-10°) are addressed. By simple inspection it is clear that steeper slopes pose a greater risk of instability than shallow gradients. Therefore, a graduated gradient scale from 0° to >12° (the practical maximum gradient on which peat is commonly observed) has been applied.

**Table E: Coefficients for Slope Gradients**

| Slope Angle (°) | Slope Angle Coefficients |
|---|---|
| Slope <2° | 1 |
| 2°≤ Slope <4° | 2 |
| 4°≤ Slope <8° | 4 |
| 8°≤ Slope <12° | 6 |
| >12° Slope | 8 |

### 5.4.3 Substrate

Table F shows the substrate type and their related substate coefficient. As noted above, most failures in thin peat layers occur at the interface with the underlying substrate; the nature of the substrate has an influence on the probable level of stability.

Peat failures often occur within glacial till deposits in which an iron pan is observed in the upper few centimetres (Dykes and Warburton, 2007)[21]. They have also been observed over glacial till without an obvious iron pan, or over impermeable bedrock. They are rarely cited over permeable bedrock as the formation of peat deposits is deemed to be less likely.

Where sand and/or gravel (derived from glacial till) form the substrate, the effective strength of the interface can be considered to be good with comparatively high friction values. Under these conditions, failure is likely to occur in a zone within the peat, just above the interface.

21 Dykes A and Warburton J (2007) Mass movements in peat: A formal classification scheme. Geomorphology 86, pp. 73–93

Statkraft Internal

Further factors are necessary to cause a failure of this nature (increased pore pressures within the peat) and occurrence of such events is rare.

A rock substrate provides a high strength stratum, however, the rock surface can be smooth, and, depending on the dip orientation of the strata, it can provide a very weak interface. Therefore, it has been given a rating higher than that of granular material.

Where clay forms the interface, there is likely to be a significant zone of softening in the clay (due to saturation at low normal stresses, poor or non-existent vertical drainage and the effect of organic acids), resulting in either very low undrained shear strength or low effective shear strength parameters. The result is that potential shearing could occur either in the peat, on the interface or in the clay; all three possibilities have been documented in the past.

**Table F: Coefficients for Substrate**

| Substrate Conditions | Substrate Coefficients |
|---|---|
| Granular | 1 |
| Rock | 2 |
| Cohesive | 3 |
| Not proven | 3 |
| Slip material (Existing materials) | 5 |

Probing across the Proposed Development indicated primarily granular and bedrock substrates using the refusal method. This was confirmed by coring at selected locations across the Proposed Development.

### 5.4.4 Results

The table of results, included in **Annex A,** shows that 6,183 probe locations were identified within the extent of the DTM, peat (>0.5 m) was present at 2,446 locations. The stability risk rating identified the following:

- No peat was recorded at 270 locations (4%), hence no risk;
- Negligible risk at 3,822 (62%) locations;
- Low risk at 1,458 (23%) locations;
- Medium risk at 612 (10%) locations; and
- High risk at 21 (<1%) locations.

**Figure 10.1.9a-f** presents the interpreted risk of peat instability based on the multiplication of the risk coefficients discussed above in Table D to Table F.

## 5.5 Impact Rating

An assessment of the receptors ‘Impact Rating’ of the medium risk locations has been undertaken. It should be noted that the impact assessment is primarily concerned with impacts that affect the environment, ecology, public or infrastructure associated with the Proposed Development, both on-site and potentially off-site. This assessment does not consider the detailed ecological impact of construction induced peat instability; however, the majority of the sensitive on-site receptors are the watercourses and thus the inferred ecological and environmental issues are addressed. The proposed mitigation measures in Section 6.0 would limit the potential for any slope failures into watercourses and drainage features hence limit such impacts. The effect a slope failure may have on the construction site and infrastructure can be easily identified. However, the effect of an instability event on features impacted by an

Statkraft Internal

event not associated with the Proposed Development is harder to predict. In order to address this effect, it is not considered appropriate to assess the effect at every potential receptor location close to the Proposed Development; but rather to assess the effect a particular infrastructure feature (track, wind turbine, substation, etc.) would have on the structures or features surrounding it. By adopting such an approach, the assessment of infrastructure features where a risk ranking of 'negligible' or 'low' (assessed in the stability risk assessments described above) is discounted from further assessment.

The impact rating coefficient (score) is derived by multiplying the receptor ranking coefficient (score) by the distance coefficient (score) and the elevation coefficient (score) for each impact receptor associated with a particular infrastructure feature. The ranking process by attributing the different weighting systems to each factor is detailed in the following sub-sections.

### 5.5.1 Receptor Ranking

Receptors are generally nearby structures or features that may be affected by peat movements caused during or following construction. Generally, only receptors immediately down gradient of the infrastructure feature could be affected by peat instability, therefore the first phase of feature ranking requires topographic ridges and valleys to be identified across the Proposed Development and surrounding area. From this, receptors at risk from particular infrastructure features can be identified. However, should instability occur on a steep slope, there is the risk of the back scarp of the instability migrating up-slope, there-by affecting areas previously considered not to be at risk.

The main receptors located within the Proposed Development and surrounding area which could potentially be affected in the event of a peat slide; were primarily watercourses and associated tributaries, existing tracks and paths and the proposed wind farm infrastructure. The feature deemed to be the receptor for each medium or high slide risk location is listed below in Table L. No GWDTE or PWS are deemed to be a receptor of any peat instability at this site.

Following identification of receptors at risk, these are ranked according to their size and sensitivity. Table G presents the coefficients placed on particular receptor types.

**Table G: Coefficients for Receptor Ranking**

| Nature of Feature | **Feature Coefficient** |
|---|---|
| Non-critical Infrastructure (including minor/private roads, estate tracks) | 1 |
| Wind Farm Infrastructure (including turbines, hardstandings, tracks, borrow pits, compounds, substation, etc.,) | 3 |
| Sensitive Hydrological Feature (including watercourses, GWDTE, PWS, etc.,) | 3 |
| Sub-Community (settlement 1-10 residents) | 6 |
| Community (settlement of >10 residents) | 8 |

### 5.5.2 Receptor Proximity

The proximity of an impact receptor is also critical in assessing the likely level of disruption it may suffer following an instability event. Based on this, two further coefficients – distance from infrastructure feature and relative elevation differences between the infrastructure feature and

Statkraft Internal

impact receptor - are applied in deriving an impact ranking. Table H and Table I present the coefficients derived for distance and elevation of impact receptors.

**Table H: Coefficient for Receptor Proximity**

| Distance from Coefficient Feature | Distance Coefficient |
|---|---|
| > 1 km | 1 |
| 100 m – <1 km | 2 |
| 10 – <100 m | 3 |
| 0 – <10 m | 4 |

**Table I: Coefficient for Impact Feature Elevation**

| Relative Elevation of Feature | Elevation Coefficient |
|---|---|
| 0 -<10 m | 1 |
| 10 – <50 m | 2 |
| 50 – <100 m | 3 |
| > 100 m | 4 |

Based on distance to impact receptors, in this instance we have identified watercourses (which are the most sensitive receptor near the Proposed Development). The other receptors have been discounted, either they are not present or distance to receptor mitigates risk. Watercourses are the principal receptor as they are at risk of not only direct impact from a peat slide but potentially the watercourse creates a pathway to impact other receptors indirectly, either ecological or potential water users downstream. Based on Table G the watercourses would have an impact receptor coefficient (score) of 3 and then considering the distance to the receptor and the relative elevation differences on-site of receptors, a potential impact can be derived.

## 5.6 Hazard Ranking

In order to achieve a meaningful and manageable result from the hazard ranking, the results of the Risk Rating and Impact Rating have been normalised to a standard numerical scale (below).

**Table J: Rating Normalisation**

| Risk Rating | | Impact Rating | |
|---|---|---|---|
| Current Scale | Normalised Scale | Current Scale | Normalised Scale |
| Negligible <5 | 1 | Very Low <10 | 1 |
| Low 5 - <16 | 2 | Low 11 - 20 | 2 |
| Medium 16 – <31 | 3 | High 21 - 30 | 3 |
| High 31 - 50 | 4 | Very High 31-50 | 4 |
| Very High >51 | 5 | Extremely High >51 | 5 |

The method of assessing probability of landslide, adverse consequence and hazard developed by SLR Consulting incorporates additional critical elements such as the substrate interface and coefficients for the receptor position, distance and elevation and as such is considered to be more rigorous than the assessment scheme proposed by the Scottish

Statkraft Internal

Government[1]. The Hazard Ranking scale does equate to the Scottish Government[1] scale, with rankings divided over four zones.

A simple multiplication of these coefficients would result in potentially large and unwieldy risk and impact rating numbers. SLR has therefore opted to normalise these values to bring them in line with the values used in the Scottish Government Guidance[1], as illustrated in Table J.

**Table K: Hazard Ranking**

| Hazard Ranking | Hazard Ranking Zone | Action |
|---|---|---|
| 1-4 | Insignificant | No mitigation action required although slide management and monitoring shall be employed.<br>Slide management shall include the development of a site specific construction plan for peat areas. |
| 5 - 10 | Significant | As for insignificant condition plus further investigation to refine the assessment combined with detailed quantitative risk assessment to determine appropriate mitigation through relocation or re-design. |
| 11 - 16 | Substantial | Consideration of avoiding project development in these areas should be made unless hazard mitigation can be put in place without significant environmental effect. |
| 17-25 | Serious | Unacceptable level of hazard; development within the area should be avoided. |

The stability risk assessment has demonstrated that the majority of the Proposed Development lies within an area of negligible to low risk (90% of probe locations) with regards to stability based on **Figure 10.1.9a-f**.

10% of probe locations identified a medium or high risk of peat instability across the Proposed Development. Following review, the majority of these locations are not considered to have either a potential impact on the development infrastructure, due to locality, either well away from influencing infrastructure, in a down gradient position or have no impact on the local watercourses (receptors). Therefore 21 medium and 3 high risk sites have been identified and are discussed in the following section.

The stability risk assessment results presented in Table L shows the calculated hazard ranking associated with every location where there is a stability risk of medium or above, at or close to infrastructure. The particular mitigation measures to reduce the risk of instability occurring are dependent upon location and the type of proposed structure. Proposed mitigation measures and actions already undertaken to reduce the risk of peat instability occurring are also identified in Table L, together with the associated, revised hazard ranking. A more detailed discussion of the possible mitigation measures is presented in Section 6.0.

Statkraft Internal

# 6.0 Slide Risk and Mitigation

## 6.1 Overview

A number of mitigation measures can be implemented to further reduce the risk levels identified across the Proposed Development site. These range from infrastructure specific measures to general good practice that should be applied across the Proposed Development to increase awareness of peat instability and enable early identification of potential displacement and opportunities for mitigation.

Risks may be mitigated by:

- Undertaking site specific stability analysis using better quality geotechnical data, final design loads for infrastructure and detailed ground models in areas of specific concern.
- Precautionary construction measures – including use of monitoring, good practice and a geotechnical risk register relevant to all locations.

Mitigation measures are provided below specific to each area of “Medium” or “High” risk. These mitigation measures will also help further reduce “Low” and “Negligible” risks to potential receptors. Section 6.2 provides information on good practice pre-construction, during construction and post-construction (i.e. during operation).

## 6.2 Embedded Mitigation

The paragraphs below detail good practice that is recommended during construction and follow the principles detailed in the NatureScot Guidance (2024)[3]. These measures are considered 'embedded mitigation' for the purposes of the assessment, and have been assumed to be in place for the purposes of the assessment presented in the EIA Report:

**Excavated Groundworks**

- Use of appropriate supporting structures around peat excavations to prevent collapse and the development of tension cracks.
- Avoid cutting trenches or aligning excavations across slopes (which may act as incipient head scarps for peat failures) unless appropriate mitigation has been put in place.
- Implement methods of working that minimise the cutting of the toes of slopes, e.g. working up-to downslope during excavation works.
- Monitor the ground upslope of excavation works for creep, heave, displacement, tension cracks, subsidence or changes in surface water content.
- Monitor cut faces for changes in water discharge, particularly at the peat-substrate contact.
- Minimise the effects of construction on natural drainage by ensuring natural drainage pathways are maintained or diverted such that there is no significant alteration of the hydrological regime of the site; drainage plans should avoid creating drainage/infiltration areas or settlement ponds towards the tops of slopes (where they may act to both load the slope and elevate pore pressures).

**Permanent Tracks**

- Maintain drainage pathways through tracks to avoid ponding of water upslope.
- Monitor the top line of excavated peat deposits for deformation post-excavation.

Statkraft Internal

- Monitor the effectiveness of cross-track drainage to ensure it water remains free-flowing and that no blockages have occurred.

**Temporary Tracks**

- Prior to the construction, setting out the centreline of the proposed track should include a walk over performed by the site manager or general foreman, along with the suitably qualified Geotechnical Engineer, and appropriate Clerk of Works. This should be carried out to check that the ground conditions/drainage paths are as expected, and "fine-tuning/micrositing" of the alignment if required.
- Weather policy should be agreed and implemented during works, e.g. identifying 'stop' rules (i.e. weather dependent criteria) for cessation of track construction or trafficking (e.g. allowing tracks to thaw following periods of hard frost).
- Allow peat to undergo primary consolidation by adopting rates of road construction appropriate to weather conditions.

**Peat Storage**

- Ensure stored peat is not located in areas identified with 'Medium' or higher peat landslide likelihoods.
- Undertake site specific stability analysis for all areas of peat storage to ensure the likelihood of destabilisation of underlying peat is minimised. Analysis should consider the slope angle of the storage location, the thickness of peat being stored and being loaded, and use representative parameters for both the stored and underlying peat.
- Avoid storage of peat in areas of peat >1 m in depth.
- Ensure adequate drainage is maintained for any peat storage areas.
- Minimise haul distances for peat, storing as near to excavation as possible.
- Monitor effects of wetting/re-wetting stored peat on surrounding peat areas, and prevent water build up on the upslope side of peat mounds. Mitigate any run-off.

**Monitoring during and post construction**

The following activities will be built into any monitoring of groundworks undertaken for the development:

- Ponding on the upslope side of infrastructure sites and on the upslope side of access tracks.
- Subsidence and lateral displacement of tracks.
- Blockage or underperformance of the installed site drainage system.
- Development of tension cracks, compression features, bulging or quaking bog anywhere in a 50 m corridor surrounding the site of any construction activities or site works.

This monitoring should be undertaken on a quarterly basis in the first year after construction, biannually in the second year after construction and annually thereafter; in the event that unanticipated ground conditions arise during construction, the frequency of these intervals should be reviewed, revised and adjusted accordingly.

**Good Practice**

In addition to these control measures, the following good practice should be followed:

Statkraft Internal

- A geotechnical risk register (GRR) should be prepared for the Proposed Development following intrusive investigations post-consent and location specific stability analyses – the risk register should be considered a live document and updated with site experience as infrastructure is constructed.
- The observation of any peat instability and pre-failure indicators should be recorded in the GRR during the setting out of proposed works.
- All construction activities and operational decisions that involve disturbance to peat deposits should be overseen by an appropriately qualified geotechnical engineer with experience of construction on peat sites.
- Awareness of peat instability and pre-failure indicators should be incorporated in site induction and training to enable all site personnel to recognise ground disturbances and features indicative of incipient instability.
- Monitoring checklists should be prepared with respect to peat instability addressing all construction activities proposed for site.
- A documented procedure shall be in place and rapid reaction strategy in place prior to the commencement of construction on peat land. This strategy shall be enacted should signs of peat movement be recorded across the Proposed Development. This approach requires periodic and continued monitoring of the construction process by a suitably qualified geotechnical engineer.
- A detailed Construction Environmental Management Plan (CEMP) shall be produced and incorporate the conclusions of the peat stability report, continuously update the assessment and develop appropriate mitigations to respond to the peat slide risk as development proceeds.
- As part of the GRR, regular inspection and monitoring of stored peat should be undertaken until temporary storage has been completed. This involves the recording of any visual signs of ground movement including identification of tension cracking or slumping of peat material. Future inspection frequency would be determined post construction and be dependent upon meteorological conditions.
- Awareness of peat instability and pre-failure indicators should be incorporated in site induction and training to enable all site personnel to recognise ground disturbances and features indicative of incipient instability.

## 6.3 Proposed Mitigation

As noted in **Figure 10.1.9a-f**, where the risk assessment has identified a negligible or low risk of peat instability, no specific mitigation measures are necessary. However, to ensure best practice is employed, there would be a need for careful monitoring and the construction management must include careful design of both the permanent and temporary works appropriate for peat soils, as detailed in Section 6.2.

The areas of the infrastructure that were rated as medium or high risk, or above, were subjected to a hazard assessment; a number of areas were discounted as they do not fall within influencing distance of any of the key proposed site infrastructure. The procedure adopted was to review the peat slide risk data and identify those areas with a medium risk or greater, that were in close proximity or influencing distance of any of the proposed infrastructure or watercourses. Those risk areas where there is no development would not affect the natural stability of the peat.

Table L lists the locations that have been identified to have a medium risk of peat instability on the Proposed Development infrastructure. A variety of mitigation measures are

Statkraft Internal

recommended to reduce the risk of peat instability. Analysis of each location has shown that all can be mitigated to a Hazard Ranking of “Insignificant”.

Statkraft Internal

**Table L: Risk Register**

| Identified Risk Location | Risk Rating | Impact Rating | Hazard Ranking | Infrastructure at Risk Zone | Key Receptor | Mitigation | Revised Hazard Ranking |
|---|---|---|---|---|---|---|---|
| 1 | Medium | Low | Significant | Access track | Existing estate track | Excavation of peat prior to construction would reduce and mitigate risk of peat landslide towards estate track. Suitable shoring of excavations would assist in mitigating risk during construction. Catch wall ditches or fences could be constructed downslope of the risk location to mitigate against any peat slide during construction works.<br>Drainage pathways should be maintained during and post construction to reduce risk of peat slide.<br>Good construction practices, as detailed in Section 6.2, should be followed to mitigate against any instability. | Insignificant |
| 2 | Medium | Low | Significant | Access track | No key receptor | Excavation of peat prior to construction would reduce and mitigate risk of peat landslide towards the west. There is no key receptor at risk of peat slide as the topography within the area forms a bowl at the base of the slope before rising again towards the west effectively containing any peat landslide.<br>Suitable shoring of excavations would assist in mitigating risk during construction. Catch wall ditches or fences could be constructed downslope of the risk location to mitigate against any peat slide during construction works.<br>Drainage pathways should be maintained during and post construction to reduce risk of peat slide.<br>Good construction practices, as detailed in Section 6.2, should be followed to mitigate against any instability. | Insignificant |
| 3 | Medium | Low | Significant | Borrow Pit | No key receptor | Excavation of peat prior to development of borrow pit would reduce and mitigate risk of peat landslide to the east.<br>There is no key receptor at risk of peat slide as the topography within the area forms a bowl at the base of the slope before rising up again towards the east. | Insignificant |

| Identified Risk Location | Risk Rating | Impact Rating | Hazard Ranking | Infrastructure at Risk Zone | Key Receptor | Mitigation | Revised Hazard Ranking |
|---|---|---|---|---|---|---|---|
| | | | | | | Good construction practices, as detailed in the Section 6.2, should be followed to mitigate against any instability. | |
| 4 | Medium | Low | Significant | Borrow Pit | No key receptor | Excavation of peat prior to development of borrow pit would reduce and mitigate risk of peat landslide to the east. Peat and soils will be stripped prior to the working of the borrow pit with suitable prevention methods put in place to stabilise cuttings.<br>There is no key receptor at risk of peat slide as the topography within the area forms a bowl at the base of the slope before rising up again towards the east.<br>Good construction practices, as detailed in Section 6.2, should be followed to mitigate against any instability. | Insignificant |
| 5 | Medium | Low | Significant | Access track | Unnamed watercourse | Excavation of peat prior to construction would reduce and mitigate risk of peat landslide towards the watercourse. Suitable shoring of excavations would assist in mitigating risk during construction. # 7.0 Conclusion

This report has highlighted the complicated inter-relationship between all the aspects that have an effect on the stability of peat. Consequently, the discussion has also addressed areas of construction and drainage in order to avoid a stability problem rather than attempt to put it right after the event. The Proposed Development has been assessed for potential hazards associated with peat instability; the assessment has been based on:

- A walk-over survey by an experienced geologist;
- A thorough inspection of the digital terrain map;
- Review of historical and geological maps and publications and aerial photography; and
- A detailed geotechnical probing exercise at 6,183 locations in areas of identified peaty soil/peat to determine the thickness thereof.

The maximum depth of recorded peat was 4.8 m bgl, recorded adjacent to Loch na Guailne in the south of the Proposed Development. The average thickness of peat recorded across the Proposed Development was 0.6 m. Probing indicated that 60% of peat probe locations encountered <0.5 m of peat. 31% of probe locations identified peat between 0.5 to 1.5 m, and the remaining 19% of probe locations encountered peat depths >1.5 m.

The results indicate that 10% of probe locations are at medium or high risk of peat instability.

The overall conclusion regarding peat stability is that there is a negligible to low risk of peat instability over most of the main site although some areas of medium and high risk have been identified. For these areas, a hazard impact assessment was completed which concluded that, subject to micro-siting and the employment of appropriate mitigation measures, all these areas can be considered as an insignificant hazard.

Additional mitigation measures have been identified in areas where hazards are already considered insignificant to further reduce the risk of potential hazards occurring.

Statkraft

N

- Site Boundary
- Proposed Turbine Location (180 m Blade Tip Height)
- Proposed Turbine Location (200 m Blade Tip Height)
- Proposed New Access Track
- Proposed Permanent Hardstanding
- Proposed Borrow Pit Search Area
- Proposed Watercourse Crossing
- Watercourse (OS Open Vector)
- Waterbody (OS Open Vector)

**Peat Slide Risk**

- Negligible
- Low
- Medium
- High
- Identified Risk Location
- Direction of Peat Slide
